EXPANDABLE INTERBODY SPINAL FUSION IMPLANTBACKGROUND OF THE INVENTION5 Field of the Invention

The present invention relates generally to an improved interbody (for placement at least in part between adjacent vertebral bodies) spinal fusion implant for the immobilization of vertebrae. In particular, the invention relates to a spinal fusion implant that is selectively directionally expandable and which specifically has height raising capabilities that are utilized once the implant is initially positioned. More particularly, the invention relates to an implant having arcuate portions of upper and lower members that have a first, collapsed position relative to one another during insertion and a second, expanded position relative to one another allowing for an increased height.

15

Description of the Related Art

Threaded and push-in spinal fusion implants having upper and lower arcuate portions adapted for placement in contact with adjacent vertebral bodies are known in the related art. The first artificial threaded spinal fusion implant was invented by Michelson and is disclosed in U.S. patent 5,015,247, filed June 13, 1988, which is hereby incorporated by reference. A push-in spinal fusion implant was invented by Michelson and is disclosed in U.S. patent 5,593,409, filed February 17, 1995, which is hereby incorporated by reference.

25

Lordotic, frusto-conical, or tapered, threaded and push-in spinal fusion implants are also known in the art. By way of example, Michelson has invented such implants as disclosed in U.S. application serial numbers 08/480,904 and EP 96917996.9, which are hereby incorporated by reference.

30

Expandable fusion implants are known in the related art. The first expandable spinal fusion (allowing for the growth of bone from vertebral body to vertebral body through the implant) implant was invented by Michelson and is disclosed in U.S. patent 5,776,199, filed June 28, 1988, which is hereby incorporated by reference.

Lordotic, frusto-conical, or tapered, spinal fusion implants have the advantage of restoring or enhancing spinal lordosis. Threaded and push-in spinal fusion implants offer the advantage of being easily positioned in the implantation space and of having excellent fastening or holding features.

5 Expandable fusion implants offer the advantage of allowing for the placement of a potentially larger implant through a smaller opening in a patient's body. Selective expansion along a single direction, (e.g. vertically only when correctly installed) offers the advantage of increasing the height of the implant and therefore the distraction of the disc space, but without a concomitant
10 increase in the width of the implant.

There exists a need for an artificial interbody spinal fusion implant providing for all of the aforementioned advantages in combination.

SUMMARY OF THE INVENTION

In accordance with the present invention, as embodied and broadly
15 described herein, there is provided an expandable artificial interbody spinal fusion implant for insertion across a disc space between two adjacent vertebral bodies of a human spine. The implant of the present invention includes an upper member having an arcuate portion adapted for placement toward and at least in part within one of the adjacent vertebral bodies and a
20 lower member having an arcuate portion adapted for placement toward and at least in part within the other of the adjacent vertebral bodies. The arcuate portions of the upper and lower members have at least one opening in communication with one another for permitting for the growth of bone from a vertebral body to an adjacent vertebral body through the implant. The upper
25 and lower members are articulated therebetween, preferably proximate one of the proximal ends and the distal ends of the upper and lower members and preferably allow for divergence between the articulating members at the end opposite the articulating end of the implant. The upper and lower members have a first position relative to one another that allows for a collapsed implant
30 height and a second position relative to one another that allows for an increased height. The arcuate portions of the upper and lower members in the first position of the present invention may be parallel or angled to one another. At least a portion of a bone-engaging projection, such as a helical

thread, ratchet, or knurling, is on the exterior of each of the opposed arcuate portions of the upper and lower members for engaging the adjacent vertebral bodies. The upper and lower members have a leading or distal end, an opposite trailing or proximal end, and a length therebetween. A blocker that is preferably in the form of an expander is located proximate at least one of the ends for holding at least a portion of the upper and lower members apart so as to maintain the increased height of the implant and resist the collapse of the implant to the collapsed implant height. Expansion of the implant preferably increases the implant height only, that is in a plane passing through the mid-longitudinal axis of the implant and the upper and lower members.

The blocker need not be in contact with the upper and lower members when the implant is initially inserted into the implantation space. The blocker may be a block or any type of spacer that is inserted between or otherwise holds apart the articulated upper and lower members after the implant is positioned so as to hold portions of the upper and lower members spaced apart the optimal height and angulation relative to one another. That is the implant may be expanded with an extrinsic tool and then the expanded portions held apart in the second position by a third body blocker or blockers placed therebetween. Further, a physician may be able to select from a series of blockers having different heights usable with the same implant. The present invention includes expanding the implant with a tool, such as a spreader or a distractor, but is not limited to a scissors type, a rack and gear type, a threaded member type or any other type of particular external expander tool mechanism. Each tool nevertheless preferably engages the upper and the lower implant members to urge the implant apart. Then the blocker may be inserted into contact with the upper and lower members to maintain the implant at an expanded height. The height of the gap created by expanding the implant may be measured so that the appropriately sized blocker or expander may be inserted into contact with the upper and lower members depending upon the amount of distraction of the implant desired by the physician.

In a preferred embodiment, the blocker is in contact with the upper and lower members prior to the implant expansion, and the blocker is itself the

expander, which may be operated by an extrinsic tool. By way of example only, the expander may rotate: to increase the height of the implant; in a single direction; more than 40 degrees and less than 140 degrees and more preferably approximately 90 degrees to move from a first insertion position to a second/deployed position; and in a plane perpendicular to the longitudinal axis of the implant to increase the height of the implant. The expander preferably remains in the same perpendicular plane relative to the longitudinal axis of the implant when rotated. In another embodiment the expander may be a member, such as a plate, a rod, or of any other configuration suitable for the intended purpose initially within the interior between the upper and lower members in a collapsed position that is erected to a more erect position when the implant is in the expanded position. The expander can be hollow or solid.

In a preferred embodiment, the expander preferably has means including, but not limited to, an opening, a projection, or a detent adapted to cooperatively engage a tool used to rotate the expander to increase the height of the implant. The opening, projection, or detent is adapted to cooperatively engage a tool that preferably rotates about an axis parallel to the longitudinal axis the implant to rotate the expander to increase the height of the implant. Rather than having an opening, a projection, a detent, or a central aperture, the expander may have two or more recesses or holes placed on or through the proximal face to engage a tool. In an alternative embodiment of the expander, cutouts may be positioned along a portion of the perimeter of the expander.

The expander is preferably located proximate at least one of the proximal end or the distal end of the upper and lower members. The expander, however, need not be so located. The expander may be spaced away from the end and even permit a hollow portion to exist on both the proximate and distal sides of the expander. The upper and lower members preferably have an interior surface therebetween and a hollow defined therein with the expander located proximate one of the longitudinal ends of that interior hollow. The hollow between the ends of the upper and lower members is preferably unobstructed by the expander so as to permit growth of bone directly through the hollow unobstructed by the expander from

vertebral body to vertebral body through the implant transverse to the longitudinal axis of the implant. The implant may comprise a second and lesser hollow extending at least in part from the expander to the end of the upper and lower members proximate that expander. A preferred expander
5 mechanism includes an expander in combination with cooperating surfaces of the end wall of the implant that guide and support the expander.

Preferred forms of interbody spinal fusion implants have a substantial hollow portion. Certain expandable interbody spinal fusion implants that increase in height only of the related art contain an expansion mechanism
10 passing longitudinally therethrough or an expansion mechanism that is configured for movement of the expansion mechanism from proximate one end of the hollow portion to proximate the other end of the hollow portion, thus requiring the expander to pass through the length of the hollow portion. A preferred embodiment of the present invention overcomes these limitations.

The expander moves the arcuate portions of the upper and lower members from a parallel orientation to an angled orientation; or a parallel orientation to an increased height parallel orientation; or an angled orientation to a parallel orientation; or an angled orientation to an increased height angled orientation that may be the same or a different angle relative to one another;
20 or from a first height at each end to a second and greater height at at least one and possibly both ends. Each of the upper and lower members may structurally cooperate with a blocker, or expander so as to keep it located so as to function for its intended purpose. By way of example, each of the upper and lower members preferably has a track within which the blocker may be
25 captured or the expander rotated. The tracks may be configured to permit the expander to rotate therein and then to move from side to side therewithin. The track of the upper member and the track of the lower member are preferably in the same plane and the plane is preferably perpendicular to the longitudinal axis of the implant.

A preferred expander has a first height in a first or insertion position and a greater second height when rotated or positioned into a second or deployed position to increase the maximum height of the implant from a first maximum height to a second maximum height. By way of example, at least
30

one of the tracks of the upper and lower members preferably has a cooperating surface and the expander has a corresponding cooperating surface that contacts the cooperating surface of the track to orient the expander in a predetermined position. The cooperating surfaces preferably orient the expander within the implant such that the axis of rotation of the expander is parallel with the longitudinal axis of the implant and, more preferably, center the expander within the implant such that the axis of rotation of the expander coincides with the longitudinal axis of the implant. As may be advantageous for the further loading of the implant with fusion-promoting material, the expander may cooperate with the tracking surfaces of the upper and lower members to allow the expander to slide from side-to-side for easier access to the implant interior.

The implant is preferably packed full of bone or other fusion-promoting substances prior to expansion of the implant. Expansion of the implant results in a space being formed in the implant interior into which additional fusion promoting substances such as bone may preferably be packed. Rotating the expander within the implant causes a void that can be filled with bone. If the expander is configured to permit side-to-side movement, then packing of additional bone into the implant is easy.

When installing a preferred implant from the posterior approach to the spine, the implant is driven from the trailing end and the expander is at the leading end at the anterior aspect of the spine. When expanded, the implant installed from the posterior aspect leaves a void at the leading end of the implant near the anterior aspect of the spine because the leading end of the implant has been made taller, the void preferably being packed with bone. Additionally, the path left behind in the bone filled interior of the implant by the tool used to access the expander through the bone filled interior to position the expander is preferably packed with bone as well.

In a preferred embodiment of the present invention, the expander height change from the first position to the second position corresponds to substantially the same change in height of the implant along at least a portion of the length of the implant. The expander may be configured in different ways. A preferred configuration for a rotational expander includes: a first

dimension corresponding to the width of the expander when the implant is initially inserted into the spine and to the height of the rotational expander when the rotational expander is rotated to increase the height of the implant; and a second dimension corresponding to the height of the expander when the implant is initially inserted into the spine and to the width of the expander when the expander is rotated to increase the height of the implant. The first dimension preferably is greater than the second dimension.

The expander may have an upper surface, a lower surface, and side surfaces as defined when the expander is positioned after rotation to increase the height of the implant. As used herein, the term "side surfaces" refers to those portions of the expander that extend from the upper member to the lower member after the expander has been rotated into its second or deployed position to increase the height of the implant. The "upper" and "lower" expander surfaces refer to those portions of the expander that are in contact with the upper and lower members when the implant is in its second or expanded configuration. Each of the upper and lower surfaces of the expander may lie generally in a plane and may be generally parallel to one another. The side surfaces and the upper and lower surfaces may be oriented so as to substantially form a parallelogram, which will typically be in the shape of a rectangle generally.

A preferred expander is in the form of a modified rectangle or rhomboid. The expander generally has a longer dimension and a shorter dimension. When the expander is in a first position, the short dimension spans the distance between the upper and lower members and when the expander is in the second position, the expander's long dimension spans the distance between the upper and lower members.

The expander may have a cross-section with the side surfaces intersecting the upper and the lower surfaces at junctions, which may be two diametrically opposed corners and two diametrically opposed arcs. The two diametrically opposed arcs may be each of the same radius and, preferably, the diagonal or modified hypotenuse "MH" between the opposed arcs has a maximum dimension that generally approximates the distance between the upper and lower surfaces such that, when the expander is rotated from a first

insertion position toward a second/deployed position, no substantial over-distractive occurs between the adjacent vertebral bodies as would occur if the height of the implant was increased markedly beyond that obtained in the second/deployed position. The two diametrically opposed corners may form a 90-degree angle. The expander preferably has a fixed shape during movement from a first insertion position to a second/deployed position within the implant.

In a preferred embodiment, a modified hypotenuse or diagonal "MH" is the dimension between the two diametrically opposed arcs that allows for the rotation of the expander from a first position to a second position without substantial over-distractive occurring during this process. The phrase "without substantial over-distractive" is defined as distracting the vertebral bodies in the range of elastic deformation and short of plastic deformation and tissue failure. To avoid any ambiguity regarding the phrase "without over-distractive," this phrase and the individual words contained therein are not being used as they may be in their normal or ordinary use, but are being used as defined in this application only. In the example of this rotational expander, the MH could be identical in length to the height thereby assuring literally no overdistractive. It may be preferred, however, to have the MH just slightly greater in length than the height to insure the stability of the expander in the expanded or second position because this would then require additional force over the stable position to derotate the expander.

In accordance with an embodiment of the present invention, a second expander may be located between the upper and lower members for moving at least a portion of the upper and lower members away from one another to increase the height of the implant as defined by the maximum distance between the arcuate portions of the upper and lower members proximate that expander. All of the features described herein for the expander may also be applicable to the second expander. Additionally, the second expander may be located proximate an end of the implant opposite the other expander, thereby providing an implant capable of being expanded at both ends of the implant. The increased height of the implant resulting from moving the two expanders may be constant or varied along the length of the implant

according to the desired configuration of the implant and the relative dimensions of the individual expanders. A given implant may be adapted to receive or cooperatively engage a series of progressively sized (taller) blockers or expanders to allow the surgeon to make a final height selection at the time of surgery.

In accordance with an embodiment of the present invention, the implant may include an expansion mechanism including the expander and at least one partial wall structure preferably located proximate an implant end that guides and holds the expander in a predetermined position.

The implant may have an overlapping step-cut wall junction between the upper and lower members, which offers as some of its advantages: increasing the lateral rigidity of the implant, holding the implant in the closed first position until expanded, and to the extent desired retaining the fusion-promoting materials within the implant. The wall junction may be either solid or perforated.

One of the upper and lower members preferably has an interior wall extending toward the other of the upper and lower members and, more preferably, has two interior walls extending from each side of the arcuate portion. The interior walls may be aligned parallel with the longitudinal axis of the implant. The other one of the upper and lower members preferably has an interior-contacting surface adapted to contact or receive the interior longitudinal wall.

By way of example, one of the upper and lower members may have a longitudinally extending interior wall, which is preferably unexposed, extending toward the other of the upper and lower members when the implant is in an initial insertion position. When the implant is in the final expanded or deployed position the implant has a preferred shape such that each of the arcuate portions of the upper and lower members are separated by at least a portion of interior wall, which in this position preferably has an exposed side.

The upper and lower members in certain embodiments are articulated to one another so one of the respective ends of the upper and lower members remain articulated while the other of the respective ends of the upper and lower members are free to move away from one another. In a preferred

embodiment, the articulating means is achieved without a third member, such as an axle shaft, for example, passing through the implant. The articulating means preferably is formed into the implant walls themselves, and in a further preference in such a way that the two-implant halves may be articulated when
5 at 90 degrees to each other. The halves then are moved, much like a book closing, toward each other prior to insertion into the implantation space in the spine. Once the upper and lower members are closed from the approximately 90 degrees articulating position, much like closing the leaves of a book, the upper and lower members of the implant are locked together at the
10 articulation so that the members will not disarticulate when in use. Other types of articulation as would be known to one of ordinary skill in the art are within the scope of the present invention.

By way of example, the upper and lower members preferably have a cooperating rotational articulation or pivot point between a proximate one of
15 the proximal end and the distal end of the upper and lower members. The cooperating rotational articulation preferably is proximate one of the proximal end and the distal end of the upper and lower members at an end opposite the expander when only one end is to be expanded. A preferred rotational articulation configuration includes cooperating brackets and projections
20 configured such that articulation therebetween occurs when the upper and lower members are substantially perpendicular to one another. Such a configuration offers the advantage that the brackets and the projections will not disengage one another when articulated for use such as insertion into the spine and subsequent expansion within a range of movement of the upper
25 and lower members resulting from the expander positioning.

When the implant is in the final or expanded position the implant may take the general form of a cylinder or frusto-conical shape split along a horizontal plane through its mid-longitudinal axis wedged upper half from lower half by an inclined plane.

30 At least one and preferably both of the upper and lower members may have a screw hole passing through the trailing end, which preferably is adapted to receive a screw passing through the end of the upper and lower members and from the interior of the implant into each of the adjacent

5 vertebral bodies to anchor the implant, further stabilize those vertebral bodies relative to each other, prevent undesirable motion at the vertebral body implant interfaces, increase the compressive load at the implant trailing end, prevent rocking and thereby to mitigate against excessive peak loads, and to more uniformly distribute loads imparted to the implant over the length of the implant to the adjacent vertebral bodies. The implant may have a side configured, when in the expanded position, to cooperate with another interbody spinal fusion implant so as to allow the pair of implants to have a reduced combined width.

10 The trailing end of the implant preferably has a tool-engaging portion, but the implant may be adapted to cooperatively engage a driver at another location or by any means as would be known to one of ordinary skill in the art. This tool-engaging portion is adapted to engage an insertion tool that holds the implant during insertion in the spine. The configuration of the tool-
15 engaging portion may be an opening, and more particularly an opening that is along the longitudinal axis of the implant to facilitate the use of an insertion tool that rotates the implant into an inserted position. It is appreciated that the tool-engaging portion need not be an opening. A hole or a blind hole, threaded or otherwise, is preferred in another embodiment. In another
20 preferred embodiment the opening preferably is a threaded slot that functions to cooperatively engage and disengage a tool for use in inserting the implant. In specific embodiments, the leading or trailing end may have wall portions, and/or be adapted to cooperatively engage a cap. Either the end wall portions or a cap may have an opening or openings that may function to hold
25 fusion-promoting materials within the implant and/or, permit vascular access and bone growth therethrough.

For an embodiment of an implant of the present invention having one expander, the main access opening is preferably at the end opposite from the expander. The main opening may be at either the distal or proximal end of
30 the implant. The end of the upper and lower members containing the expander may serve as a secondary access opening.

By way of example, an implant configured for insertion from an anterior approach may be initially packed from the distal or leading end of the implant.

The implant is then driven into position. Once the expander is moved into final position and any associated tool for positioning the expander is withdrawn from the expander, any void in the bone packed into the implant interior may be filled. The expander may be moved from side-to-side to pack
5 more bone into the implant. In essence, the side-to-side movement of the expander provides for a secondary access opening for accessing the hollow interior of the implant and for compressively loading it with fusion-promoting substances.

The accompanying drawings, which are incorporated in and constitute
10 a part of this specification, are by way of example only and not limitation, and illustrate several embodiments of the invention, which together with the description, serve to explain the principles of the invention. The scope of the invention is limited only by the scope of the claims as from the present teachings other embodiments of the present invention shall be apparent to
15 those skilled in the art.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

The following description is intended to be representative only and not limiting and many variations can be anticipated according to these teachings, which are included within the scope of this inventive teaching. Reference will
5 now be made in detail to the preferred embodiments of this invention, examples of which are illustrated in the accompanying drawings.

Shown in Figs. 1-7 and 10-13, in accordance with the present invention, as embodied and broadly described herein, is one embodiment of an expandable artificial interbody spinal fusion implant 100 for anterior
10 insertion across a disc space D between two adjacent vertebral bodies V of a human spine. Implant 100 of the present invention includes an upper member 102 having an arcuate portion 104 adapted for placement toward and at least in part within the upper of the adjacent vertebral bodies V and a lower member 106 having an arcuate portion 108 adapted for placement toward and
15 at least in part within the lower of the adjacent vertebral bodies V. Arcuate portions 104, 108 of upper and lower members 102, 106 have at least one opening 110, 112 in communication with one another for permitting for the growth of bone from vertebral body V to adjacent vertebral body V through implant 100. Upper and lower members 102, 106 are articulated
20 therebetween at an adjacent one of the proximal ends and the distal ends of upper and lower members 102, 106 and allow for rotation between the articulating members at the end opposite the articulating end of implant 100. Upper and lower members 102, 106 have a first position relative to one another that allows for a collapsed implant height and a second position
25 relative to one another that allows for an increased height. Arcuate portions 104, 108 of upper and lower members 102, 106 in the first position of the present invention are parallel to one another and form at least a portion of a cylinder along the length of implant 100. A bone-engaging projection 114, 116 in the form of a portion of at least one thread 118 is on an exterior 120 of
30 each of opposed arcuate portions 104, 108 of upper and lower members 102, 106 for engaging adjacent vertebral bodies V.

While a specialized form of a blocker 121 is described in significant detail below with reference to expander 122, blocker 121 need not be in

contact with upper and lower members 102,106 when implant 100 is initially inserted into the implantation space. Blocker 121 may be a block or any type of spacer that is inserted between the articulated upper and lower members 102, 106 after implant 100 is positioned so as to hold portions of the upper and lower members 102, 106 spaced apart the optimal height and angulation relative to one another. That is the implant may be expanded with an extrinsic tool and then the expanded portions held apart in the second position by a third body blocker placed therebetween. Further, a physician may be able to select from a series of blockers having different heights usable with the same implant. The present invention includes expanding the implant with a tool, such as a spreader or a distractor but is not limited to a scissors type, a rack and gear type, a threaded member type or any other specific type of movement mechanism. Each tool nevertheless preferably engages upper and lower implant members 102, 106 to urge them apart. Blocker 121 is then inserted into contact with upper and lower members 102, 106 to maintain implant 100 at an expanded height. The height of the gap created by expanding implant 100 may be measured so that the appropriately sized blocker 121 or specialized blocker, expander 122, may be inserted in implant 100 depending upon the amount of distraction of implant 100 desired by the surgeon.

Blocker 121 that is preferably in the form of expander 122 is located proximate at least one of the ends of the implant upper and lower members 102, 106 and holds at least a portion of upper and lower members 102, 106 apart so as to maintain the increased height of implant 100 and resist the collapse of implant 100 to the collapsed implant height. Expander 122 in the present embodiment increases the implant height as measured in a plane passing through the mid-longitudinal axis of implant 100 and upper and lower members 102, 106 during positioning of expander 122 and as may be desirable is capable of selectively increasing the height of the implant only.

Expander 122 in the present embodiment is adapted to rotate in a single direction approximately 90 degrees to move from an initial (first) insertion position I, as best shown in Figs. 1, 3 and 10, to a final (second) deployed or expanded position F, as best shown in Fig. 13, to increase the

maximum height H of implant 100. Expander 122 preferably rotates in a plane perpendicular to the longitudinal axis L of implant 100 to increase the maximum height H of implant 100. During rotation, expander 122 remains in the same perpendicular plane relative to the longitudinal axis L of the implant.

5 It is appreciated that an expander within the scope of the present invention may be designed to: rotate in either direction or both directions; rotate more than 40 degrees and less than 140 degrees; rotate more or less than 90 degrees; or rotate in a plane other than perpendicular.

Expander 122 has an opening 124 adapted to cooperatively engage a
10 tool (not shown) used to rotate expander 122 to increase height H of implant 100. Opening 124 is adapted to cooperatively engage a tool that preferably rotates about an axis parallel to the longitudinal axis L of implant 100 to rotate expander 122 to increase height H of implant 100. Opening 124 also may be used as a passageway to pass fusion-promoting substances through
15 expander 122 and into implant 100. It is appreciated that the expander may also include a projection, a detent, or any other configuration in place of or in addition to an opening so as to cooperatively engage a tool to move the expander.

In an alternative embodiment, expander 122 could have cutouts along
20 any portion of its perimeter not involved in the actual rotation as shown in Fig. 1A. In another alternative embodiment, a blocker 121 having cutouts along a portion of its perimeter can be positioned into the implant as shown in Fig. 1B. The cutouts can be used to engage a raised area within the implant to lock blocker 121 or expander 122 into position or be used by the surgeon to grasp
25 blocker 121 with a tool that cooperatively engages the cutouts to facilitate inserting blocker 121 into the implant. Rather than having an opening, a projection, a detent, or a central aperture, blocker 121 alternatively could have two or more recesses or holes placed on or through the proximal face to engage a tool as shown in Fig. 1C.

30 As shown in Figs. 1, 6, 7, 10, 12A-12C, and 13, in one preferred embodiment of the present invention for anterior insertion, expander 122 is located proximate the trailing end 126 of upper and lower members 102, 106. While in a second embodiment as shown in Figs. 14-16 for posterior insertion

expander 222 is located proximate the leading end 250. As shown in Figs. 17-19, in third and fourth embodiments of the present invention for anterior insertion and possible use together, expanders 322 are located proximate each of leading and trailing ends 350, 326 of implants 300.

5 Implant 100 preferably has an interior surface 128 and a hollow 130 defined therein. Expander 122 of the present embodiment is located proximate interior surface 128 and more particularly proximate interior surface 128 at trailing end 126 of upper and lower members 102, 106. As is preferred, hollow 130 between the ends is unobstructed by expander 122 so
10 as to allow for the unimpeded loading of the interior of the implant with the desired fusion-promoting substances; thus, loading the implant is easy. Further, this preferred configuration of implant 100 makes available all of the volume of the hollow to contain fusion-promoting substances and so as to permit for the growth of bone directly through the hollow unobstructed by the
15 expander to adjacent vertebral bodies V. Unobstructed hollow 130 further allows for packing implant 100 with fusion-promoting substances. It is appreciated that depending on the intended results, the expander also may be located at distal end 126 or leading end 150 of upper and lower members 102, 106 or anywhere else within the implant. The unobstructed hollow
20 preferably has no mechanism extending along the longitudinal axis of the implant when finally deployed and the mechanism that moves the implant from a first position to a second position preferably does not move expander 122 longitudinally through the hollow portion. The expander may work by pivoting on a surface in contact with an interior wall portion of at least one of
25 the upper and lower members 102, 106. Moreover, multiple expanders may be used in contact with upper and lower members 102, 106 at any location within the implant.

 An alternative embodiment of an expander used with the present invention includes an expander having an external thread that cooperates with
30 converging threaded portions of the upper and lower members 102, 106 to expand the implant as the expander is rotated into position. Another alternative embodiment of an expander includes an expander having a cam configuration to expand the implant upon rotation.

The mechanism or tool used to move the expander is not part of the implant itself as the mechanism or tool is removed from the implant upon moving the expander, for example, such as to rotate it into place and thus expand the implant to the final expanded position.

5 Expander 122 of the present embodiment moves arcuate portions 104, 108 of upper and lower members 102, 106 from a parallel orientation P, as shown in Figs. 1 and 11 where implant 100 has a generally circular cross section in a first position at trailing end 126, to an angled orientation A, as shown in Fig. 12B where implant 100 has a generally oblong cross section at
10 trailing end 126, in a second position. The implant need not be a true cylinder as a cross section need not form a complete circle having portions of the perimeter absent, less round, flattered, or other. It is appreciated that the expander also may move the arcuate portions of the upper and lower members from a first height at each end to a second and greater height at
15 each end.

 In this embodiment, each of upper and lower members 102, 106 structurally cooperate with expander 122 so as to keep it located so as to function for its intended purpose. Each of upper and lower members 102, 106 of the implant of Fig. 1 has a track 132, 134 within which expander 122
20 rotates. As best shown in Figs. 1 and 13, track 132, 134 is configured to permit expander 122 to rotate therein and then to move from side to side within track 132, 134. Track 132 of upper member 102 and track 134 of lower member 106 are in the same plane and the plane is perpendicular to the longitudinal axis of implant 100. It is appreciated that the track of the upper
25 and lower members may be in different planes. Such a track design may be used with an expander with a step in it or with offset tabs to engage tracks in different planes than one another. As with the expander, the tracks also may be at various angles to the longitudinal axis of the implant including parallel with the longitudinal axis of the implant. Other means for respectively
30 engaging the implants and the expander position thereof are anticipated and within the scope of the present invention.

 In rotating the expander, the longer dimension of the expander is substituted for the lesser dimension of the expander thus correspondingly

increasing the maximum height of the implant from the first to the second position. As best shown in Fig. 9, the schematic representation of a geometric configuration of a cross-section of an expander 122 in accordance with one embodiment of the present invention, includes: a first dimension X corresponding to the height of expander 122 when implant 100 is initially inserted into the spine and to the width of expander 122 when expander 122 is rotated to increase height H of implant 100; and a second dimension Y corresponding to the width of expander 122 when implant 100 is initially inserted into the spine and to the height of expander 122 when expander 122 is rotated to increase height H of implant 100. Second dimension Y is greater than first dimension X. Expander 122 has an upper surface 136, a lower surface 138, and side surfaces 140 as defined when expander 122 is positioned after rotation to increase height H of implant 100. As used herein, the term "side surfaces" refers to those portions of expander 122 that extend from upper member 102 to lower members 106 after expander 122 has been rotated into its final deployed, or second position to increase the height H of implant 100. The "upper" and "lower" surfaces refer to those portions of expander 122 that are in contact with upper and lower members 102, 106 when implant 100 is in its second position and configuration and is fully expanded.

A preferred expander 122 is in the form of a modified rectangle or rhomboid. The expander generally has a longer dimension Y and a shorter dimension X. When the expander is inserted into a first position, the short dimension X spans the distance between upper to the lower members 102, 106 and when expander 122 is in the second position, the longer dimension Y of expander 122 spans the distance between upper and lower members 102, 106.

Expander 122 in one embodiment of the present embodiment has a cross-section with side surfaces 140 intersecting upper and lower surfaces 136, 138 at two junctions which may be diametrically opposed corners 142 and two diametrically opposed arcs 144. Arcs 144 are preferably each of the same radius and the modified hypotenuse MH between opposed arcs 144 generally approximates the distance between upper and lower surfaces 136,

138 such that, when expander 122 is rotated from an initial insertion position toward a final deployed position, no substantial over-distraction occurs between adjacent vertebral bodies V.

5 The modified hypotenuse MH of this embodiment of the present invention may be equal, slightly less than, or slightly greater than dimension Y of expander 122. Having the modified hypotenuse MH be slightly greater than the dimension Y offers the advantage of having expander 122 stabilized by an over-center position, such that more energy would be required to derotate the expander than for it to remain in the deployed or second position. By "without
10 substantial over-distraction" what is meant is that the modified hypotenuse MH length is closer to the expander dimension Y than to the unmodified hypotenuse UH; and is selected to allow the implant to preferably operate in the range of elastic deformation of the tissues about the operated disc space. Corners 142 may form, but not necessarily, a 90-degree angle and have an
15 unmodified hypotenuse dimension UH.

By way of example, consider one embodiment of expandable implant 100 of the present invention having an optimum expanded height of 18 mm for a given implantation space. Any implant bigger than 18 mm should not be used in this implantation space because during expansion of the implant, its
20 height would move through the range of elastic deformation of the surrounding tissues and after that the implant would crush the vertebral bone or tear ligaments. Inserting an expander such that when the implant is fully expanded allows the implant to be 18 mm would be ideal. It may be that an implant having a 17.5 mm expanded height for this implantation space is
25 nearly as good, but a 16 mm expanded height may be too short to fit tightly within the implantation space. Using a preferred rectangular expander without any modification to the hypotenuse that is adapted to expand the implant to the optimum 18mm final height would require the expander to have a hypotenuse causing the implant to exceed the 18 mm expanded height
30 temporarily during rotation of the expander. So turning the expander without a modified hypotenuse would break the vertebrae or tear the ligaments. In reverse, if one could not expand the implant to more than 18 mm without causing damage to the spine, then an implant selected to have an expander

having a full unmodified hypotenuse so as to upon rotation temporarily cause the implant height to be 18 mm would in the finally expanded position allow the implant height to collapse such that there would be insufficient height for the implant to adequately distract the implantation space. Generally, the
5 modified hypotenuse of the expander is closer in length to dimension Y of the expander than to the unmodified hypotenuse.

As best shown in Fig.1 in this particular embodiment, expander 122 has a depth dimension Z that is less than that of first and second dimensions Y, X. Expander 122 of the present embodiment has a fixed shape during
10 movement from initial insertion position I to final deployed position F within implant 100.

As shown in Figs. 22A, 22B, and 23, blocker 121 may also take the form of a trailing wall that articulates or hinges to the inside of implant 100. The trailing wall may be left open during insertion of implant 100 so as to trail
15 behind the upper and lower members. The trailing wall does not protrude outside of a projection rearward of the circumference of implant 100. Once implant 100 is implanted into position, the trailing wall is rotated about one of its ends and pushed into position and locked into place. This may occur by having the trailing wall contact an inclined plane that leads up to a notch into
20 which the trailing wall locks into place. The trailing wall itself may also have at least one opening in it to permit the further loading of fusion-promoting materials into implant 100.

While modified hypotenuse MH is illustrated as being between arcs 144 in this preferred embodiment, the configuration of expander 122 to form
25 modified hypotenuse MH can take many forms, such that those junctions are relieved so as to have the desired lesser dimension therebetween, including arcs, chamfers, a series of angled surfaces, or any other shape so long as the modified hypotenuse MH is sufficiently reduced in dimension to function for the intended purpose according to the present teaching.

30 An embodiment of the present invention where modified hypotenuse MH is slightly greater than height Y offers the advantage of an over-center effect that locks expander 122 into place. In this instance, once expander 122 rotates past the diagonal of the modified hypotenuse MH, more force would

be required to rotate it back from the final deployed position to its insertion position than in an embodiment where modified hypotenuse MH is equal to or less than height Y. Preferably, expander 122 offers a surgeon multiple sensory advantages including: the tactile feel of expander 122 going over
5 center and locking into place; the visual of the handle of a tool rotating expander 122 such that the tool handle goes from perpendicular to parallel, the reverse, or other, to the disc space into place; and auditory from the sound of expander 122 snapping into place.

Each of upper and lower surfaces 136, 138 of expander 122 of the
10 present embodiment lie generally in a plane and are generally parallel to one another. For any implant it is anticipated that a physician may be able to select from a series of blockers or expanders allowing for varying the increase in the implant height. Side surfaces 140 and upper and lower surfaces 136,
138 are oriented so as to substantially form a parallelogram. Any of a number
15 of configurations for the expander for increasing the height of the implant is possible, based on the teachings of the present application and such configurations as would be known to one of skill in the art are anticipated within the scope of the present invention.

The implant may preferably have an overlapping step-cut wall junction
20 between upper and power members 102, 106 which offers the advantage of increasing the lateral rigidity of implant 100 holding the implant in the closed first position until expanded, and to the extent desired retaining the fusion-promoting materials within. The wall junction may be either solid or perforated. As best shown in Fig. 1, upper member 102 in one embodiment
25 of the preferred invention has interior walls 146 extending from each side of arcuate portion 104 toward lower member 106. Interior wall 146 is aligned parallel to longitudinal axis L of implant 100. Lower member 106 has an interior-contacting surface 148 adapted to contact or receive interior wall 146.

In a preferred embodiment, upper and lower members 102, 106 are
30 articulated to one another so one of the respective ends of upper and lower members 102, 106 remain articulated while the other of the respective ends of upper and lower members 102, 106 are free to move away from one another. In a preferred embodiment the articulating means is achieved without a third

member such as an axle shaft passing through the implant. The articulating means preferably is formed into the implant walls themselves in such a way that the two implant halves may be articulated when the halves are at 90 degrees to each other and then the halves are moved toward each other for
5 insertion into the implantation space in the spine. The two halves are closed much like the cover of a book. The halves are locked together such that disarticulation will not occur when the implant is assembled for use. Any of a number of ways of articulating or joining upper and lower members 102, 106 is possible.

10 As best shown in Fig. 1 in this embodiment, upper and lower members 102, 106 of the present embodiment have a pivot point between adjacent distal ends 126 or leading ends 150 of upper and lower members 102, 106. The pivot point in the present embodiment is at the end of implant 100 opposite expander 122. The pivot point of the present embodiment operates
15 as a hinge or axle 152 but is formed out of the walls themselves so as to preferably not intrude into the implant interior or hollow or to block access thereto. Hinge 152 includes a projection 154 extending radially from each side of arcuate portion 108 of lower member 106 and a slotted bracket 156 extending from each side of arcuate portion 104 of upper member 102 for
20 engaging projection 154. Brackets 156 and projections 154 are configured such that engagement occurs when upper and lower members 102, 106 are substantially perpendicular to one another. Brackets 156 and projections 154 are configured so as not to disengage within a range of movement of upper and lower members 102, 106 that would occur when the implant is in use
25 either during insertion or resulting from the expansion in height of implant 100.

As best shown in Fig. 11, interior wall 146 of upper member 102 of the present embodiment is unexposed when implant 100 is in initial insertion position I. As shown in Fig. 12C, when implant 100 is in the expanded
position F, implant 100 has a shape such that each of arcuate portions 104,
30 108 of upper and lower members 102, 106 are separated by at least a portion of interior wall 146, which in this position has an exposed side. The exposed side of the present embodiment is smooth and flat.

As best shown in Fig. 8, a cap 158 having an exterior surface 160 and an interior surface 162 is used to close leading end 150 of implant 100. Interior surface 162 of cap 158 has spaced slots 164 about its circumference to facilitate a snap fit between cap 158 and implant 100. Cap 158 and implant 100 can of course be adapted for either or both ends of implant 100.

As discussed above, implant 100 has a leading end 150 and a trailing end 126. One of the ends preferably has a tool-engaging portion. This tool-engaging portion is adapted to engage an insertion tool that holds and rotates implant 100 into position. The tool-engaging configuration may be an opening, and more particularly an opening that is along the longitudinal axis of the implant to facilitate the use of an insertion tool that rotates implant 100 into an inserted position. Of course, the tool-engaging portion need not be an opening. A hole or a blind hole, threaded or otherwise, is preferred in another embodiment. In another preferred embodiment the opening preferably is a threaded slot that functions to cooperatively engage and disengage a tool for use in inserting implant 100. The opening either alone on the proximal end of implant 100 or in conjunction with other openings on the proximal end function to hold fusion-promoting material in implant 100 while permitting vascular access and bone growth through the opening or openings.

Implants of the present invention may have an end adapted to cooperatively engage an implant driver. The anterior approach implant may have a leading end, trailing end, or both ends that are adapted to engage a cap. One of the purposes for that cap includes restricting the passage of fusion-promoting substances so that they remain loaded within the implant. Another purpose of the cap may be to add structural support to the implant. The cap may be solid or it may have openings therethrough. Any such openings could allow for the loaded material to stay within the implant while providing for vascular access to allow for the ingrowth of blood vessels and the growth of bone through the end of the implant.

For a posterior approach implant the cap may be on either or both ends. The trailing end of the implant in a posterior approach implant has direct exposure to the spinal canal where the spinal cord and nerve roots are located. A cap on a posterior approach implant may be for the purpose of

sealing off the spinal canal from the fusion-promoting substances contained in the hollow interior of the implant so that no bone grows into the canal.

Further, the present invention implant may be used in combination with chemical substances and/or compounds applied at the trailing end of the implant to inhibit scar formation, and the cap may be of benefit in shielding the fusion-promoting substances contained in the implant from these scar formation inhibiting chemicals and compounds. It may also be for the purposes identified herein used in association with the leading end cap of an anterior approach implant.

Shown in Figs. 14-16, in accordance with the present invention, as embodied and broadly described herein, is a second embodiment of an expandable threaded artificial interbody spinal fusion implant 200 for posterior insertion across a disc space D between two adjacent vertebral bodies V of a human spine. Threaded implant 200 of the present invention includes an upper member 202 having an arcuate portion 204 adapted for placement toward and at least in part within the upper of the adjacent vertebral bodies V and a lower member 206 having an arcuate portion 208 adapted for placement toward and at least in part within the lower of the adjacent vertebral bodies V. Implant 200 in Figs. 14 and 15 is shown being implanted into the spine from the posterior aspect with expander 222 on the distal end 226 or leading end 250 of implant 200. While anterior and posterior aspect approaches have been illustrated herein, the present invention is not limited to these illustrated approaches. In particular, but not limited thereto, the threaded implant of the present invention also may be used in threaded implants for insertion from the translateral aspect of the spine as disclosed by Michelson in U.S. patent 5,860,973, which is incorporated herein by reference.

As best shown in Fig. 16, tracks 232, 234 of upper and lower members 202, 206 of the second embodiment have a cooperating surface 266 and expander 222 has a corresponding cooperating surface 268 that contacts cooperating surface 266 of tracks 232, 234 to orient expander 222 in a predetermined location. The cooperating surfaces orient expander 222 within implant 200 such that the axis of rotation of expander 222 is parallel to the

longitudinal axis of implant 200 and more particularly center expander 222 within implant 200 such that the axis of rotation of expander 222 coincides with longitudinal axis L of implant 200.

5 Tracks 232, 234 include sides 270 having cooperating surface 266 and expander 222 has corresponding cooperating surface 268 used to orient expander 122 in a predetermined location. Cooperating surface 266 of side 270 is a detent and corresponding cooperating surface 268 of expander 222 is a projection. The projection preferably projects away from expander 222 in a direction parallel to the longitudinal axis of implant 200. The detent and the
10 the projection preferably center expander 222 within implant 200 such that the axis of rotation of expander 222 coincides with the longitudinal axis of implant 200.

Shown in Figs. 17-19, in accordance with the present invention, as embodied and broadly described herein, is a third embodiment of an
15 expandable threaded artificial interbody spinal fusion implant 300 for insertion across a disc space D between two adjacent vertebral bodies V of a human spine. Threaded implant 300 of the present invention includes an upper member 302 having an arcuate portion 626 for orientation toward the upper of adjacent vertebral bodies V and a lower member 306 having an arcuate
20 portion 308 for orientation toward the lower of the adjacent vertebral bodies V.

Implant 300 of the present embodiment may include any of the various features disclosed in association with implant 100 and implant 200 disclosed herein. Implant 300 further includes a side surface 372 contoured to cooperatively receive another implant. See U.S. patent 5,593,409 by
25 Michelson for a discussion of the advantages associated with placing implants in side-in-side contact.

Another aspect of implant 300 is that its upper and lower members 302, 306 have screw holes 374 passing therethrough adapted to receive a screw 378 passing from the interior of implant 300 into adjacent vertebral
30 bodies V to anchor implant 300 to an adjacent vertebral body V.

The articulation may be of one of two general types, examples of which are each herein disclosed. As shown in previously described embodiments of the present invention, the articulation may allow rotation about the articulation.

A second type of articulation allows for both rotation and expansion at the point of articulation. An example of this is shown in Fig. 19, where a peg and hook design is utilized. While in this example both functions, that is rotation or pivoting, and captured or limited expansion with a fixed end point or stop, occur at the same location. Alternatively, and without departing from the teachings of the present invention, those functions can be divided. By way of example only, and not limitation, expansion can be allowed and controlled by an interlocking wall design, as shown by the interlocking members in the alternative embodiments of Figs. 20 and 21. Various other structural features as would be obvious to one of ordinary skill in the art after the teachings herein can similarly be employed.

A fixed end point for the implant expansion is preferred for the proper functioning of the opposed bone screws. A purpose of the opposed bone screws is to rigidly secure the implant within the vertebral segment. A further purpose is to pull each of the adjacent vertebral bodies toward the implant and towards each other so as to have a construct resistant to the deleterious effects of vertebral rocking as may otherwise occur with spinal flexion and extension absent such restraint. If the articulation device captured the upper and lower members together, as in the embodiments of Fig. 1-16, by closely encircling a post then the implant could not expand at that location. So the coupling mechanism of Fig. 19 permits the upper and lower members to remain articulated, permits the implant to expand, and permits the screws to pull against the implant and each other, in opposite directions and to pull the bones toward each other. The optional extended slot and peg configuration on the right-hand side of Fig. 19 illustrated in dashed image lines is not needed to hold the implant together.

In accordance with this embodiment of the present invention, a second expander may be located at least in part between the upper and lower members for moving at least a portion of the upper and lower members away from one another to increase the height of the implant defined by the maximum distance between the arcuate portions of the upper and lower members. All of the features described herein for the expander may also be applicable to the second expander. Additionally, the second expander may

be located proximate an end of the implant opposite the other expander, thereby providing an implant capable of being expanded at both ends of implant. The increased height of the implant resulting from moving the two expanders may be the constant or varied along the length of the implant according to the desired configuration of the implant.

Figs. 24-29 show a preferred embodiment of an expandable interbody spinal fusion implant 400 and an expanding and locking end cap 500 for use therewith in accordance with the present invention. As shown in Figs. 24 and 25, implant 400 preferably has a leading end 450, a trailing end 426, an upper member 402, and a lower member 406. Upper and lower members 402, 406 are each preferably arcuate at least in part and adapted for placement toward and at least in part within the upper and lower of two adjacent vertebral bodies, respectively. Each of upper and lower members 402, 406 preferably have at least one opening 410, 412 in communication with one another for permitting for the growth of bone from adjacent vertebral body to adjacent vertebral body through implant 400. Trailing end 426 preferably includes openings 480 to permit for the growth of bone through implant 400.

Implant 400 has a bone-engaging projection 414 that is preferably an external helical thread to permit for the rotational insertion of implant 400 into the disc space and between adjacent vertebral bodies of a human spine. Although a preferred embodiment of the implant has threads, the invention is not so limited. For example, the exterior of implant 400 may have other bone-engaging projections such as splines, knurling, or other surfaces roughenings to resist expulsion of the implant from the disc space after implantation.

As shown in Figs. 27 and 28, by way of example, upper and lower members 402, 406 preferably have a cooperating rotational articulation or pivot point 452 between upper and lower members 402, 406. The cooperating rotational articulation 452 preferably is proximate one of the proximal end and the distal end of upper and lower members 402, 406 at an end opposite to an end cap 500. Upper and lower members 402, 406 preferably have upper and lower screw holes 474 passing therethrough, each adapted to receive a bone screw 478 passing from the interior of implant 400 into an adjacent vertebral body to anchor implant 400 to an adjacent vertebral

body. Bone screws are not essential to the operation of the invention, but are preferable for providing added securement of the implant to the adjacent vertebral bodies.

5 In certain circumstances, upper and lower members 402, 406 can move away from one another and merely securing upper and lower members 402, 406 to the adjacent vertebral bodies with bone screws is not adequate. An example of such a circumstance occurs when the surgeon elects to approach the spine anteriorly, which generally requires severing and/or removing substantial portions of the anterior longitudinal ligament over the
10 operated area. The anterior longitudinal ligament is positioned along the anterior spinal surface and prevents hyperextension of the spine as an individual bends backward. Because the anterior longitudinal ligament covers the anterior spinal surface, the surgeon must cut through this tough ligament to access the disc space below, compromising the stability of the spine. Specifically, the anterior longitudinal ligament is generally lax, except when an
15 individual leans backward, then the ligament acts as a tension band resisting elongation. If the anterior longitudinal ligament is damaged, there is no check on that spinal movement and the vertebral bodies may detrimentally angulate. Thus, a mechanism is needed to prevent movement of the upper and lower
20 members relative to one another beyond a predetermined amount.

Figs. 24-25 show expanding and locking end cap 500 for use with implant 400. The end cap is capable of one or more of the following functions: (1) expands the implant by moving the upper and lower members apart, (2) maintains the implant in an expanded state by holding at least a
25 portion of the upper and lower members apart so as to maintain the increased height of the implant and resist the collapse of the implant to the collapsed implant height, (3) prevents the implant from expanding beyond a predetermined amount by engaging at least a portion of the upper and lower members, and (4) locks bone screws to the implant by blocking the exit path
30 of the bone screws in a direction opposite to the direction of insertion. Expansion of the implant preferably increases the implant height only, that is in a plane passing through the mid-longitudinal axis of the implant and the

upper and lower members. In a preferred embodiment, the end cap is capable of performing all four of the aforementioned functions.

As shown in Figs. 24 and 25, trailing end 126 of implant 400 preferably has an opening 482 adapted to engage cap 500 and may also provide access
5 to the interior of implant 400 for the purpose of introducing bone growth promoting materials therein. Upper and lower interior surfaces 484, 486 of opening 482 preferably have a portion that extends beyond exterior trailing end surface 488, forming upper lip portions 490 and lower lip portions 492, respectively. When implant 400 is in an unexpanded state, the profile of
10 upper and lower lip portions 490, 492 preferably form the shape of at least a portion of an oval. In the expanded state of implant 400, the profile of upper and lower lip portions 490, 492 preferably becomes less oval and generally more circular in shape. For example, upper and lower lip portions 490, 492 can be arcs of a circle such that in the expanded state, the arcs would be part
15 of the same circle.

Cap 500 has a head 502 and a stem 504. Head 502 has a perimeter preferably sized and shaped to cover at least a portion of upper and lower bone screw holes 474 so as to lock bone screws 478 to implant 400. Head 502 has a top surface 506, a bottom surface 508, and a rim 510. Top surface
20 506 has a tool engagement area 512 that is preferably adapted to cooperatively engage an insertion tool. Tool engagement area 512 preferably includes a hex-shaped recess 514 and a groove 516 adapted to engage correspondingly-shaped tools, respectively. Other shapes are possible for tool engagement area 512 depending upon the type of insertion tool used with
25 the present invention, all of which are within the broad scope of the present invention.

Top surface 506 of cap 500 preferably has a bevel 518 extending around the perimeter thereof to form a reduced profile. Top surface 506 may have any shape suitable for its intended purpose and it is preferable that such
30 shape does not extend from trailing end 426 so as not to substantially interfere with delicate vascular and neurological structures adjacent thereto after implant 400 is installed in the spine.

As shown in Fig. 24A, bottom surface 508 of cap 500 has a recess 520 proximate the perimeter of bottom surface 508 that is adapted to interact with upper and lower lip portions 490, 492 of implant 400. As described in further detail below, the interaction of lip portions 490, 492 and recess 520 limits the over-expansion of implant 400. Recess 520 has an inner perimeter 522, an outer perimeter 524, and a width therebetween adapted to accommodate the profiles of at least a portion of upper and lower lips 490, 492 of implant 400 in both an unexpanded and expanded state. The surface of outer perimeter 524 forms a flange that acts as a stop against which upper and lower lip portions 490, 492 of implant 400 are prevented from further movement away from the mid-longitudinal axis of implant 400 when implant 400 and cap 500 are engaged, as will be described in more detail below.

Stem 504 of cap 500 projects from bottom surface 508 and is sized and shaped to cooperatively engage opening 482 in trailing end 426 to expand implant 400 and to maintain implant 400 in an expanded state. Stem 504 preferably has a distal end 526 with tabs 528, 530, an upper surface 532, a lower surface 534 opposite to upper surface 532, and sides 536, 538. Tabs 528, 530 are configured to engage the interior surface of trailing end 126 such that when properly positioned within opening 482, tabs 528, 530 prevent cap 500 from backing out of opening 482 of implant 400.

Sides 536, 538 of stem 504 are configured to cooperatively engage upper and lower interior surfaces 484, 486 of opening 482. Opening 482 may have any shape suitable for its intended purpose for interacting with stem 504. For example, sides 536, 538 may be beveled or rounded to accommodate rotational contact with upper and lower interior surfaces 484, 486. Stem 504 may have a generally rectangular cross-section or may have a cross-section with sides 536, 538 intersecting the upper and the lower surfaces 532, 534 at junctions, which may be two diametrically opposed corners and two diametrically opposed arcs. The two diametrically opposed arcs may be each of the same radius and, preferably, the diagonal or modified hypotenuse "MH" between the opposed arcs has a maximum dimension that generally approximates the distance between the upper and lower surfaces 532, 534 such that, when stem 504 is rotated from a first insertion position toward a

second/deployed position, no substantial over-distraction occurs between the adjacent vertebral bodies as would occur if the height of the implant was increased markedly beyond that obtained in the second/deployed position.

The two diametrically opposed corners may form a 90-degree angle.

5 Additionally, sides 536, 538 may be configured to be divergent away from distal end 526 to better accommodate engagement with upper and lower interior surfaces 484, 486 while implant 400 is in the expanded state.

Figs. 26-28 show a preferred expansion of implant 400 by cap 500. In Fig. 27, stem 504 of cap 500 is inserted through opening 482 in trailing end 426 of implant 400. After stem 504 is inserted into opening 482, tabs 528, 530 extend beyond upper and lower interior surfaces 484, 486 of opening 482 and into the interior of implant 400. Upper and lower surfaces 532, 534 of stem 504 are oriented toward upper and lower interior surfaces 484, 486 of opening 482, respectively, such that implant 400 is in a collapsed state. As cap 500 is rotated 90° in either direction, sides 536, 538 of stem 504 cooperatively engage with upper and lower interior surfaces 484, 486 of opening 482, forcing apart upper and lower members 402, 406 away from the mid-longitudinal axis of implant 400 to position implant 400 in an expanded state. The rotation of cap 500 moves upper and lower members 402, 406 from a generally parallel orientation shown in Fig. 27 to an angled orientation shown in Fig. 28. During expansion of implant 400, upper and lower lip portions 490, 492 move within recess 520 of cap 500 until stem 504 ceases moving upper and lower interior surfaces 484, 486 away from the mid-longitudinal axis of implant 400.

25 Fig. 29 shows a partial cross-section along line 29--29 of Fig. 26. As shown in Fig. 29, the maximum expansion of upper member 402 is reached when upper lip portions 490 are blocked from further motion away from the mid-longitudinal axis of implant 400 upon reaching outer perimeter 524 of recess 520. Although not shown in Fig. 29, lower lip portions 492 similarly contact outer perimeter 524 of recess 520. In this manner, the expansion of implant 400 beyond a predetermined amount is prevented. Tabs 528, 530 of stem 504 bear against the interior of implant 400 and prevent removal of end

cap 500 from opening 482. In the deployed position, end cap 500 locks implant 400 in an expanded state.

As shown in Figs. 30-33, another preferred embodiment of the implant and end cap of the present invention is shown and generally referred to by the reference numbers 600 and 700, respectively. Implant 600 is similar to
5 implant 400, except that opening 682 of implant trailing end 626 preferably has at least one thread 694 for cooperatively engaging with a threaded stem 404 of cap 700.

Cap 700 is similar to cap 500, except for differences noted below.
10 Head 702 includes an upper cutout portion 740 and a lower cutout portion 742, each being adapted to allow the passage of a bone screw 678 into implant 600 after cap 700 has been attached to implant 600. Once bone screws 678 are inserted, cap 500 may be rotated such that at least a portion of head 702 covers each of screws 678. Upper and lower cutout portions
15 740, 742 allow the surgeon the option of inserting bone screws 678 before or after attachment of cap 700 with implant 600.

Stem 704 has at least one thread 748 along the mid-longitudinal axis of cap 700 for cooperatively engaging with threaded opening 682 of implant 600. Distal end 726 of stem 704 has an upper surface 744 and a lower surface 746
20 that are convergent towards distal end 726 for assisting in the insertion of stem 704 into opening 682 of implant 600.

As shown in Figs. 32 and 33, cap 700 is inserted into trailing end 626 of implant 600, preferably by aligning the edge of distal end 726 with the plane separating upper and lower members 602, 606. Once upper and lower
25 surfaces 744, 746 of distal end 726 are sufficiently within threaded opening 682 of implant trailing end 626, cap 700 is rotated to allow stem thread 748 of cap 700 to cooperatively engage with threaded opening 682. The engagement of stem thread 748 with threaded opening 682 spreads apart upper and lower members 602, 606 at least along a portion of the length of
30 implant 600. Continued rotation of cap 700 forces upper and lower lip portions 690, 692 to contact recess 720 of cap 700. The pitch of thread 748 is preferably such that as upper and lower lip portions 690, 692 reach recess 720, they come into contact with at least a portion of the outer perimeter of

recess 720. Upon contact with recess 720, upper and lower lip portions 690, 692 are prevented from further movement away from the mid-longitudinal axis of implant 600.

Those skilled in the art will appreciate that although it is preferred to use a cap to prevent over-expansion of an expandable implant, the invention is not so limited. For example, the implant trailing end may be adapted to have lip portions along the trailing end interior surface for cooperatively engaging with a recess and/or flange to prevent over-expansion of the implant. In such an instance, an over-expansion inhibiting surface may operate without a stem and/or head by relying on additional surface features of the implant trailing end, for example, a key-way entry along the opening leading to the interior lip portions or a circumferential barrier beyond the interior lip portions for preventing the over-expansion surface from traveling too far into the implant interior. Although the expander implant cap has been described with respect to a threaded expanding spinal fusion implant, it may be adapted for use with any expandable spinal implants including any of the various implant embodiments disclosed herein. Shown in Figs. 34-36B, in accordance with the present invention, as embodied and broadly described herein, is another embodiment of an expandable threaded artificial interbody spinal fusion implant 800 for anterior insertion across a disc space D between two adjacent vertebral bodies V of a human spine. Implant 800 of the present invention includes an upper member 802 having an arcuate portion 804 adapted for placement toward and at least in part within the upper of the adjacent vertebral bodies V and a lower member 806 having an arcuate portion 808 adapted for placement toward and at least in part within the lower of the adjacent vertebral bodies V. Arcuate portions 804, 808 of upper and lower members 802, 806 in the first position of the present invention are angled to one another and form at least a portion of a frusto-conical shape along the length of implant 800. A bone engaging projection 814, which is preferably formed of at least one thread is on an exterior of each of opposed arcuate portions 804, 808 of upper and lower members 802, 806 for engaging adjacent vertebral bodies V.

As shown in Figs. 36A and 36B, in one preferred embodiment of the present invention for anterior insertion, expander 822 is located proximate the trailing end 826 of upper and lower members 802, 806. Expander 822 moves arcuate portions 804, 808 of upper and lower members 802, 806 from a first angled orientation A, as shown in Figs. 35 and 36A in a first position, to a second angled orientation A', as shown in Fig. 36B where implant 800 has a generally oblong cross section at trailing end 826, in a second position. The implant of the present invention need not be a true frusto-conical shape as a cross section need not form a complete circle but may have portions of the perimeter absent, less round, flattened including flattened on two or more sides, or other. It is appreciated that the expander also may move the arcuate portions of the upper and lower members from a first height at each end to a second and greater height at each end.

Shown in Figs. 37-39 is another embodiment of an implant of the present invention for posterior insertion with expander 922 located proximate the leading end 950. As shown in Fig. 37, implant 900 may be angled or tapered so as to converge from trailing end to leading end when in the collapsed position for insertion into the spine. The taper on implant 900 may facilitate its insertion. Alternatively, as shown in Fig. 38, the implant of the present invention may be angled or tapered so as to diverge from trailing end to leading end when in the collapsed position for insertion into the spine. For an implant with an angle that diverges for trailing end to leading end, the leading end may have a chamfer or other configuration to reduce the size of the leading end to facilitate insertion of the implant into the spine.

Shown in Figs. 40, in accordance with the present invention, as embodied and broadly described herein, is yet another embodiment of an expandable threaded artificial interbody spinal fusion implant 1000 for insertion across a disc space D between two adjacent vertebral bodies V of a human spine. Threaded implant 1000 of the present invention includes an upper member 1002 having an arcuate portion 1004 for orientation toward the upper of adjacent vertebral bodies V and a lower member 1006 having an arcuate portion 1008 for orientation toward the lower of the adjacent vertebral bodies V. Implant 1000 further includes a side surface 1072 contoured to

cooperatively receive another implant. Another aspect of implant 1000 is that its upper and lower members 1002, 1006 have screw holes 1074 passing therethrough adapted to receive a screw 1078 passing from the interior of implant 1000 into adjacent vertebral bodies V to anchor implant 1000 to an adjacent vertebral body V.

Shown in Figs. 41-50B, in accordance with the present invention, as embodied and broadly described herein, is one embodiment of an expandable artificial interbody spinal fusion implant 1100 for anterior insertion across a disc space D between two adjacent vertebral bodies V of a human spine.

Push-in implant 1100 of the present invention includes an upper member 1102 having an arcuate portion 1104 adapted for placement toward and at least in part within the upper of the adjacent vertebral bodies V and a lower member 1106 having an arcuate portion 1108 adapted for placement toward and at least in part within the lower of the adjacent vertebral bodies V.

Arcuate portions 1104, 1108 of upper and lower members 1102, 1106 in the first position of the present invention are parallel to one another and form at least a portion of a cylinder along the length of implant 1100. On an exterior 1120 of each of opposed arcuate portions 1104, 1108 of upper and lower members 1102, 1106 is a portion 1114, 1116 of at least one bone-engaging projection 1118 adapted for linear insertion, which in one preferred embodiment is a ratchet. As shown in Figs. 50A and 50B, expander 1122 is located proximate the trailing end 1126 of upper and lower members 1102, 1106.

Shown in Figs. 43-47, in accordance with the present invention, as embodied and broadly described herein, is one embodiment of an expandable artificial interbody spinal fusion implant 1100' for anterior insertion across a disc space D between two adjacent vertebral bodies V of a human spine.

Implant 1100' of Figs. 43, 44, 46, and 47 has a similar configuration to that of implant 1100 of Fig. 41, except that it has portions of its perimeter flattened or truncated so as to have a truncated medial side 1117' and truncated lateral side 1119'. As best shown in Figs. 44 and 47, medial side 1117' is truncated to a greater extent than lateral side 1119'. Alternatively, the medial side 1117' could be truncated to a lesser extent than lateral side 1119'. Fig. 45 shows an

embodiment of the present invention with implant 1100" having medial side 1117" truncated to approximately the same extent as lateral side 1119'.

Implant 1100' has a major diameter or height equal to the distance between bone-engaging projects 1118' on opposed arcuate portions 1104', 1108'. The width of implant 1100' is equal to the distance between a flattened segment and a point diametrically opposite the flattened segment, such as the distance between the medial side 1117' and lateral side 1119'. The effect of having at least one of medial side 1117' and lateral side 1119' truncated or reduced is that the width of implant 1100' is substantially reduced while the major diameter or height of implant 1100' is maintained.

Fig. 51 shows another embodiment of the implant of the present invention for posterior insertion adapted for expansion proximate the leading end 1250. Implant 1200 is being implanted into the spine from the posterior aspect with expander 1222 on the leading end 1250 of implant 1200. While anterior and posterior aspect approaches have been illustrated herein, the present invention is not limited to these illustrated approaches. In particular, but not limited thereto, the push-in implant of the present invention also may be used in push-in implants for insertion from the translateral aspect of the spine as disclosed by Michelson in U.S. patent 5,860,973, which is incorporated herein by reference.

Fig. 52 shows a pair of side-by-side implants 1300 having a truncated medial side 1317 and a truncated lateral side 1319, respectively. The implants are implanted across the disc space with the medial sides facing and adjacent to another implant such that the combined overall width of the two spinal implants is less than twice the major diameter or height of the implants.

Shown in Figs. 53-57B, in accordance with the present invention, as embodied and broadly described herein, is yet another embodiment of an expandable artificial interbody spinal fusion implant 1400 for anterior insertion across a disc space D between two adjacent vertebral bodies V of a human spine. Arcuate portions 1404, 1408 of upper and lower members 1402, 1406 in the first position of the present invention are angled to one another and form at least a portion of a frusto-conical shape along the length of implant 1400. While preferred embodiments of the present invention illustrated in the

attached figures and discussed herein have arcuate portions 1404, 1408 angled to one another to form at least a portion of a frusto-conical shape along the length of implant 1400, the arcuate portions may also form at least a portion of a shape described as a cylinder split along a horizontal plane through its mid-longitudinal axis wedged upper half from lower half by an inclined plane or any variation thereof suitable for the intended purpose of the expandable implant having upper and lower arcuate portions of the present invention.

Shown in Figs. 58-60 is another embodiment of an implant of the present invention for posterior insertion with expander 1522 located proximate the leading end 1550. As shown in Fig. 58, implant 1500 may be angled or tapered so as to converge from trailing end to leading end when in the collapsed position for insertion into the spine. The taper on implant 1500 may facilitate its insertion. Alternatively, as shown in Fig. 59, the implant of the present invention may be angled or tapered so as to diverge from trailing end to leading end when in the collapsed position for insertion into the spine. For an implant with an angle that diverges for trailing end to leading end, the leading end may have a chamfer or other configuration to reduce the size of the leading end to facilitate insertion of the implant into the spine.

The expandable spinal fusion implant may be made of artificial or naturally occurring materials suitable for implantation in the human spine. The implant can comprise bone including, but not limited to, cortical bone. The implant can also be formed of material other than bone, such as metal including, but not limited to, titanium and its alloys or ASTM material, surgical grade plastics, plastic composites, ceramics, or other materials suitable for use as a spinal fusion implant. The plastics may be bioabsorbable. The spinal fusion implant of the present invention can further be formed of bone growth promoting materials, including but not limited to, bone morphogenetic proteins, hydroxyapatite, and genes coding for the production of bone. The implant can be treated with a bone growth promoting substance, can be a source of osteogenesis, or can be at least in part bioabsorbable. The implant of the present invention can be formed of a porous material.

The expandable spinal fusion implant of the present invention may be coated with, comprised of, be used in combination with, or have a hollow for containing bone growth promoting materials, including but not limited to, bone morphogenetic proteins, hydroxyapatite, and genes coding for the production of bone. The spinal fusion implant of the present invention can be formed of a material that intrinsically participates in the growth of bone from one of adjacent vertebral bodies V to the other of adjacent vertebral bodies V.

While various embodiments of the present invention are presented by way of example only and not limitation, common to each of them, is that the expandable spinal fusion implant for insertion across disc space D between two adjacent vertebral bodies V of a human spine has an upper member having an arcuate portion adapted for placement toward and at least in part within the upper of the adjacent vertebral bodies V. The implant also has a lower member having an arcuate portion adapted for placement toward and at least in part within the lower of the adjacent vertebral bodies V. The arcuate portions of the upper and lower members have at least one opening. The openings of the upper and lower members are in communication with one another to permit for the growth of bone from vertebral body V to adjacent vertebral body V through the implant. At least a portion of a bone-engaging projection for engaging adjacent vertebral bodies V is on the exterior of each of the opposed arcuate portions of the upper and lower members. A blocker in the form of an expander preferably is located proximate at least one of the ends to hold at least a portion of the upper and lower members apart from one another to increase the implant height. There is disclosed in the above description and the drawings implants, which fully and effectively accomplish the objectives of this invention. However, it will be apparent that variations and modifications of the disclosed embodiments may be made without departing from the principles of the invention or the scope of the appended claims.

WHAT IS CLAIMED IS:

1. An interbody spinal fusion implant for insertion across a disc space between two adjacent vertebral bodies of a spine, said implant comprising:
 - an upper member having a portion being at least in part arcuate adapted for placement toward and at least in part within one of the adjacent vertebral bodies, said upper member having at least one opening adapted to communicate with one of the adjacent vertebral bodies, said upper member having a proximal end and a distal end;
 - a lower member having a portion being at least in part arcuate adapted for placement toward and at least in part within the other of the adjacent vertebral bodies, said lower member having at least one opening adapted to communicate with the other of the adjacent vertebral bodies, said openings of said upper and lower members being in communication with one another and adapted for permitting for the growth of bone from adjacent vertebral body to adjacent vertebral body through said implant and being sufficiently sized and located to allow for interbody spinal fusion through said implant, said lower member having a proximal end and a distal end corresponding to said proximal end and said distal end of said upper member, respectively, and a length between said proximal and distal ends, said upper and lower members articulating therebetween adjacent one of said proximal ends and said distal ends of said upper and lower members and allowing for expansion of the height of said implant, said upper and lower members having a first position relative to one another allowing for a collapsed implant height and a second position relative to one another allowing for an increased height;
 - at least a portion of a bone-engaging projection formed on the exterior of each of said opposed arcuate portions of said upper and lower members for engaging the adjacent vertebral bodies and to facilitate securing said implant into the spine; and
 - at least one blocker adapted to cooperatively engage and hold at least a portion of said upper and lower members apart so as to maintain the increased height of said implant and resist the collapse of said implant to the collapsed implant height when said implant is in a final deployed position.

AMENDED CLAIMS

[received by the International Bureau on 16 July 2001 (16.07.01);
original claims 4-11, 13-21, 23-26, 28-39, 41-45, 47-50, 53-60, 62-65, 67-77, 79, 80, 82-87, 89, 90,
92-94, 96, 97, 99, 100-104, and 106-110 amended; remaining claims unchanged (15 pages)]

2. The implant of claim 1, wherein said bone-engaging projection is at least a portion of a helical thread to facilitate securing said implant into the spine by at least in part rotating said implant about the longitudinal axis of said implant.
3. The implant of claim 1, wherein said bone-engaging projection is adapted for linear insertion.
4. The implant of any one of the preceding claims, wherein said arcuate portions of said upper and lower members in the first position are parallel to one another over a substantial portion of the length of said implant and form at least a portion of a cylinder along the length of said implant.
5. The implant of any one of claims 1, 2, and 3, wherein said arcuate portions of said upper and lower members in the first position are angled to one another over a substantial portion of the length of said implant and form at least a portion of a frusto-conical shape along the length of said implant.
6. The implant of either claim 1 or 3, wherein said arcuate portions of said upper and lower members in the first position are angled to one another over a substantial portion of the length of said implant and form at least a portion of the shape of a cylinder split along a horizontal plane through its mid-longitudinal axis with said upper member and said lower member being angled to each other along the length of said implant.
7. The implant of any one of the preceding claims, further comprising a second interbody spinal fusion implant comprising:
an upper member having a portion being at least in part arcuate adapted for placement toward and at least in part within one of the adjacent vertebral bodies, said upper member having at least one opening adapted to communicate with one of the adjacent vertebral bodies, said upper member having a proximal end and a distal end;

a lower member having a portion being at least in part arcuate adapted for placement toward and at least in part within the other of the adjacent vertebral bodies, said lower member having at least one opening adapted to communicate with the other of the adjacent vertebral bodies, said openings of said upper and lower members being in communication with one another and adapted for permitting for the growth of bone from adjacent vertebral body to adjacent vertebral body through said implant and being sufficiently sized and located to allow for interbody spinal fusion through said implant, said lower member having a proximal end and a distal end corresponding to said proximal end and said distal end of said upper member, respectively, and a length between said proximal and distal ends; and

at least a portion of a bone-engaging projection formed on the exterior of each of said opposed arcuate portions of said upper and lower members for penetrably engaging the adjacent vertebral bodies and to facilitate securing said implant into the spine, said first and second implants when in side-to-side contact having a combined width substantially less than the combined heights as measured from the upper to the lower bone-engaging surfaces of said first and second implants.

8. The implant of any one of the preceding claims, wherein said blocker pivotally attaches to one of said upper and lower members and is adapted to pivot into cooperative engagement with another of said one of said upper and lower members, said blocker being adapted to hold at least a portion of said upper and lower members apart so as to maintain the increased height of said implant and resist the collapse of said implant to the collapsed implant height when said implant is in a final deployed position

9. The implant of any one of the preceding claims, wherein said implant having a width and said blocker having a width less than the width of said implant.

10. The implant of any one of the preceding claims, wherein said blocker is a portion of one of said ends of said upper and lower members.

11. The implant of any one of the preceding claims, further comprising a hollow defined between said upper and lower members in communication with said openings in each of said upper and lower members, said hollow being adapted to receive fusion-promoting substances.
12. The implant of claim 11, wherein said hollow has a width that is unobstructed by any mechanism for moving said blocker.
13. The implant of either claim 11 or 12, further comprising a second hollow between said upper and lower member located between said blocker and said end of said implant proximate said blocker.
14. The implant of any one of the preceding claims, wherein said implant has a constant width in both the first position and the second position.
15. The implant of any one of the preceding claims, wherein said blocker is located at least in part between said upper and lower members.
16. The implant of any one of the preceding claims, wherein said blocker is located at a predetermined location along the length of said implant and remains at the predetermined location in transitioning said implant from said first position to said second position.
17. The implant of any one of the preceding claims, wherein said blocker is located proximate at least one of said ends of said upper and lower members.
18. The implant of any one of the preceding claims, wherein said blocker is adapted to cooperatively engage a tool used to move said blocker from an initial position to a final position to increase the height of said implant, said tool not being a part of said implant and being removed from said implant after moving said blocker into the final position.

19. The implant of any one of the preceding claims, wherein said implant has side walls and said blocker does not contact said side walls when said implant is in the final deployed position.
20. The implant of any one of the preceding claims, wherein each of said upper and lower members are adapted to cooperate with and to fixedly locate said blocker.
21. The implant of any one of the preceding claims, wherein each of said upper and lower members have a track configured to permit said blocker to seat therein.
22. The implant of claim 21, wherein at least one of said tracks and said blocker are adapted to cooperate with each other to center said blocker along a longitudinal axis of said implant in at least the first position.
23. The implant of any one of claims 1 through 4 and 7 through 22, wherein said blocker moves said arcuate portions of said upper and lower members from a parallel orientation to an angled orientation relative to one another.
24. The implant of any one of claims 1 through 3 and 5 through 22, wherein said blocker moves said arcuate portions of said upper and lower members from a first angled orientation to a second angled orientation relative to one another.
25. The implant of any one of the preceding claims, further comprising a second blocker located between said upper and lower members for holding at least a portion of the upper and lower members apart where said second expander is located.
26. The implant of any one of the preceding claims, wherein said blocker is an expander adapted to expand said implant from a first collapsed height to a second expanded height when moved from a first to a second position.

27. The implant of claim 26, wherein said implant has a longitudinal axis and said expander rotates in a plane generally perpendicular to the longitudinal axis of said implant to increase the height of said implant.
28. The implant of either claim 26 or 27, wherein said expander is located along the length of said implant.
29. The implant of any one of claims 26 through 28, wherein said expander is located proximate said proximal ends of said upper and lower members.
30. The implant of any one of claims 26 through 28, wherein said expander is located proximate said distal ends of said upper and lower members.
31. The implant of any one of claims 1 through 10 and 14 through 30, further comprising a hollow defined between said upper and lower members in communication with said openings in each of said upper and lower members, said hollow being adapted to receive fusion-promoting substances, said hollow being substantially unobstructed by said expander extending along a substantial portion of the length of said hollow so as to permit growth of bone from adjacent vertebral body to adjacent vertebral body through said implant.
32. The implant of any one of claims 26 through 31, wherein said expander remains in the same location along the longitudinal axis of the implant when rotated.
33. The implant of any one of claims 26 through 32, wherein said expander is located at a predetermined location along the length of said implant and remains so located in transitioning said implant from the first position to the second position.
34. The implant of any one of claims 26 through 33, wherein said expander is adapted to cooperatively engage a tool used to move said expander from an

initial position to a final position to increase the height of said implant, said tool not being a part of said implant and being removed from said implant after moving said expander into the final position.

35. The implant of any one of claims 26 through 34, wherein said expander is adapted to cooperatively engage a tool that rotates about an axis parallel to the longitudinal axis of said implant to rotate said expander to increase the height of said implant.

36. The implant of any one of claims 26 through 35, wherein said expander moves said arcuate portions of said upper and lower members from a parallel orientation to an angled orientation relative to one another.

37. The implant of any one of claims 26 through 35, wherein said expander moves said arcuate portions of said upper and lower members from a first angled orientation to a second angled orientation relative to one another.

38. The implant of any one of claims 26 through 37, wherein each of said upper and lower members are adapted to cooperate with said expander.

39. The implant of any one of claims 26 through 38, wherein each of said upper and lower members have a track configured to permit said expander to rotate therein.

40. The implant of claim 39, wherein said tracks permit said expander to move from side to side within said track.

41. The implant of either claim 39 or 40, wherein said track of said upper member and said track of said lower member are in the same plane.

42. The implant of any one of claims 39 through 41, wherein said track of said upper member and said track of said lower member are parallel to one another.

43. The implant of any one of claims 39 through 42, where said track of said upper member and said track of said lower member are in a plane perpendicular to the longitudinal axis of said implant.

44. The implant of any one of claims 39 through 43, wherein said upper and lower members structurally cooperate with said expander so as to keep said expander located within said implant.

45. The implant of any one of claims 39 through 44, wherein at least one of said tracks of said upper and lower members has a cooperating surface, said expander having a corresponding cooperating surface that contacts said cooperating surface of said at least one track to orient said expander in a predetermined location.

46. The implant of claim 45, wherein said cooperating surfaces orient said expander within said implant such that the axis of rotation of said expander is parallel with the longitudinal axis of said implant.

47. The implant of either claim 45 or 46, wherein said cooperating surfaces center said expander within said implant such that the axis of rotation of said expander coincides with the longitudinal axis of said implant.

48. The implant of any one of the preceding claims, wherein said upper and lower members are configured to cooperate with one another so as to stop said upper and lower members from being moved apart from one another more than a predetermined distance.

49. The implant of any one of claims 26 through 48, wherein said upper and lower portions are adapted to cooperate with said expander so as to center said expander within a cross section of the upper and lower portions in at least the first position.

50. The implant of any one of claims 39 through 49, wherein at least one of said tracks of said upper and lower members includes at least one side

having a cooperating surface, said expander having a corresponding cooperating surface that contacts said cooperating surface of said at least one side to orient said expander in a predetermined location.

51. The implant of claim 50, wherein said cooperating surface of said at least one side is a detent and said corresponding cooperating surface of said expander is a projection.

52. The implant of claim 51, wherein said detent and said projection center said expander within said implant such that the axis of rotation of said expander coincides with the longitudinal axis of said implant.

53. The implant of any one of claims 26 through 52, wherein said expander has a first height corresponding to the height of said expander when said implant is initially inserted into the spine, said expander having a second height corresponding to the height of said expander when said expander is moved into a final deployed position to increase the height of said implant, said second height being greater than said first height.

54. The implant of any one of claims 26 through 53, wherein said expander has an upper surface, a lower surface, and side surfaces as defined when said expander is positioned to increase the height of said implant, said side surfaces intersecting said upper and said lower surfaces at two pairs of diametrically opposed junctions.

55. The implant of any one of claims 26 through 54, wherein said two pairs of diametrically opposed junctions of said expander are a pair of diametrically opposed corners and a pair of diametrically opposed arcs.

56. The implant of either claim 54 or 55, wherein each of said upper and lower surfaces of said expander lie generally in a plane.

57. The implant of any one of claims 54 through 56, wherein said upper and lower surfaces of said expander are generally parallel to one another.

58. The implant of any one of claims 54 through 57, wherein said side surfaces and said upper and lower surfaces of said expander are oriented to have a shape substantially that of a parallelogram.

59. The implant of any one of claims 26 through 58, wherein the difference between said first height and said second height of said expander approximates the difference in height of said implant between said first position and said second position as measured proximate the location of said expander.

60. The implant of any one of claims 55 through 59, wherein said two diametrically opposed arcs are each of the same radius.

61. The implant of claim 60, wherein the distance across said two diametrically opposed arcs generally approximates the distance between said upper and lower surfaces of said expander.

62. The implant of any one of claims 55 through 61, wherein said two diametrically opposed corners form a 90-degree angle.

63. The implant of any one of claims 26 through 62, wherein said expander has a depth dimension less than that of said first and second height of said expander.

64. The implant of any one of claims 26 through 63, wherein said expander has a fixed shape during movement from an initial insertion position to a final deployed position within said implant.

65. The implant of any one of claims 26 through 64, further comprising a second expander located between said upper and lower members for moving at least a portion of the upper and lower members away from one another to increase the maximum height of said implant where said second expander is located.

66. The implant of claim 65, wherein said second expander rotates to increase the height of said implant.

67. The implant of either claim 65 or 66, wherein said second expander is located proximate an end of said implant opposite said end of said implant where said first expander is located.

68. The implant of any one of claims 65 through 67, wherein said implant has a longitudinal axis and said second expander rotates in a plane perpendicular to the longitudinal axis of said implant to increase the height of said implant.

69. The implant of any one of claims 65 through 68, wherein said hollow is substantially unobstructed by said second expander extending along a substantial portion of the length of said hollow so as to permit growth of bone from adjacent vertebral body to adjacent vertebral body through said implant.

70. The implant of any one of claims 65 through 69, wherein said second expander remains in the same location along the longitudinal axis of the implant when rotated.

71. The implant of any one of claims 65 through 70, further comprising at least a second hollow between said upper and lower member located between said second expander and said end of said implant proximate said second expander.

72. The implant of any one of claims 65 through 71, wherein each of said upper and lower members have a track within which said second expander rotates.

73. The implant of any one of claims 65 through 72, wherein said track is configured to permit said second expander to rotate therein and then to move from side to side within said track.

74. The implant of any one of claims 65 through 73, wherein said second expander has a first height corresponding to the height of said second expander when said implant is initially inserted into the spine, said second expander having a second height corresponding to the height of said second expander when said second expander is moved into a final deployed position to increase the height of said implant, said second height being greater than said first height.

75. The implant of any one of claims 65 through 74, wherein said second expander has an upper surface, a lower surface, and side surfaces as defined when said second expander is positioned to increase the height of said implant, and said side surfaces intersecting said upper and said lower surfaces at two diametrically opposed junctions.

76. The implant of any one of claims 65 through 75, wherein the difference between said first height and said second height of said second expander approximates the difference in height of said implant between said first position and said second position as measured proximate the location of said second expander.

77. The implant of any one of the preceding claims, wherein said upper and lower members have walls contacting one another.

78. The implant of claim 77, wherein said walls are aligned parallel with the longitudinal axis of said implant.

79. The implant of either claim 77 or 78, wherein said walls are at least in part overlapping.

80. The implant of any one of the preceding claims, wherein said upper and lower members have a rotational articulation therebetween adjacent one of said proximal end and said distal end of said upper and lower members.

81. The implant of claim 80, wherein said rotational articulation is at one of said proximal end and said distal end of said upper and lower members opposite said blocker.

82. The implant of either claim 80 or 81, wherein said rotational articulation allows for expansion.

83. The implant of any one of claims 80 through 82, wherein said rotational articulation allows for limited expansion.

84. The implant of any one of claims 80 through 83, wherein said rotational articulation is formed by said upper and lower members interdigitating so as to cooperatively engage.

85. The implant of any one of claims 80 through 84, wherein said rotational articulation is configured such that to permit articulation and disarticulation engagement occurs when said upper and lower members are substantially perpendicular to one another.

86. The implant of any one of claims 80 through 85, wherein said rotational articulation is configured to remain engaged within a range of movement of said upper and lower members resulting from positioning said implant in the second position.

87. The implant of any one of the preceding claims, wherein one of said upper and lower members has an interior wall, which is unexposed, extending therefrom toward the other of said upper and lower members when said implant is in an initial insertion position, and when said implant is in a final

position said implant has a shape such that each of said arcuate portions of said upper and lower members are separated by at least a portion of said interior wall, which now has an exposed side.

88. The implant of claim 87, wherein said upper and lower members have side walls for engaging each other.

89. The implant of either claim 87 or 88, wherein said side walls of said upper and lower members are at least partially overlapping walls.

90. The implant of any one of the preceding claims, wherein said implant has an interior, at least one of said upper and lower members has a screw hole passing therethrough adapted to receive a screw passing from said interior of said implant into one of the adjacent vertebral bodies.

91. The implant of claim 90, wherein each of said upper and lower members has at least one screw hole passing therethrough adapted to receive a screw passing from said interior of said implant into the adjacent vertebral body in contact with each of said upper and lower members respectively.

92. The implant of either claim 90 or 91, further comprising at least one screw adapted to pass from said interior of said implant through said screw hole and into the adjacent vertebral body to anchor said implant to the adjacent vertebral body.

93. The implant of any one of the preceding claims, wherein said implant has a side surface when in a final position that is contoured to cooperate with another implant.

94. The implant of any one of the preceding claims, further comprising a cap for closing one of said proximal end and said distal end of said upper and lower members, said cap having an exterior surface and an interior surface.

95. The implant of claim 94, wherein said interior surface of said cap has spaced slots about its circumference to facilitate a snap fit of said cap into said implant.

96. The implant of any one of the preceding claims, wherein said implant is made of an artificial material that is harder than bone.

97. The implant of any one of claims 1 through 95, wherein said implant comprises bone.

98. The implant of claim 97, wherein said bone includes cortical bone.

99. The implant of any one of the preceding claims, wherein said implant comprises bone growth promoting material.

100. The implant of claim 99, wherein said bone growth promoting material is selected from one of bone morphogenetic protein, hydroxyapatite, and genes coding for the production of bone.

101. The implant of any one of the preceding claims, wherein said implant is treated with a bone growth promoting substance.

102. The implant of any one of the preceding claims, wherein said implant is a source of osteogenesis.

103. The implant of any one of the preceding claims, wherein said implant is at least in part bioabsorbable.

104. The implant of any one of the preceding claims, wherein said implant comprises metal.

105. The implant of claim 104, wherein said metal is ASTM material suitable for use in said spinal fusion implant.

106. The implant of any one of the preceding claims, wherein said implant comprises a material selected from one of plastic and ceramic.

107. The implant of any one of the preceding claims, wherein said implant is formed of a porous material.

108. The implant of any one of the preceding claims, wherein said implant is formed of a material that intrinsically participates in the growth of bone from adjacent vertebral body to adjacent vertebral body through said implant.

109. The implant of any one of the preceding claims, wherein said implant has an interior surface and a hollow defined therein, said hollow being capable of containing bone growth promoting material.

110. The implant of any one of the preceding claims, in combination with a chemical substance to inhibit scar formation.
